

Agenda.

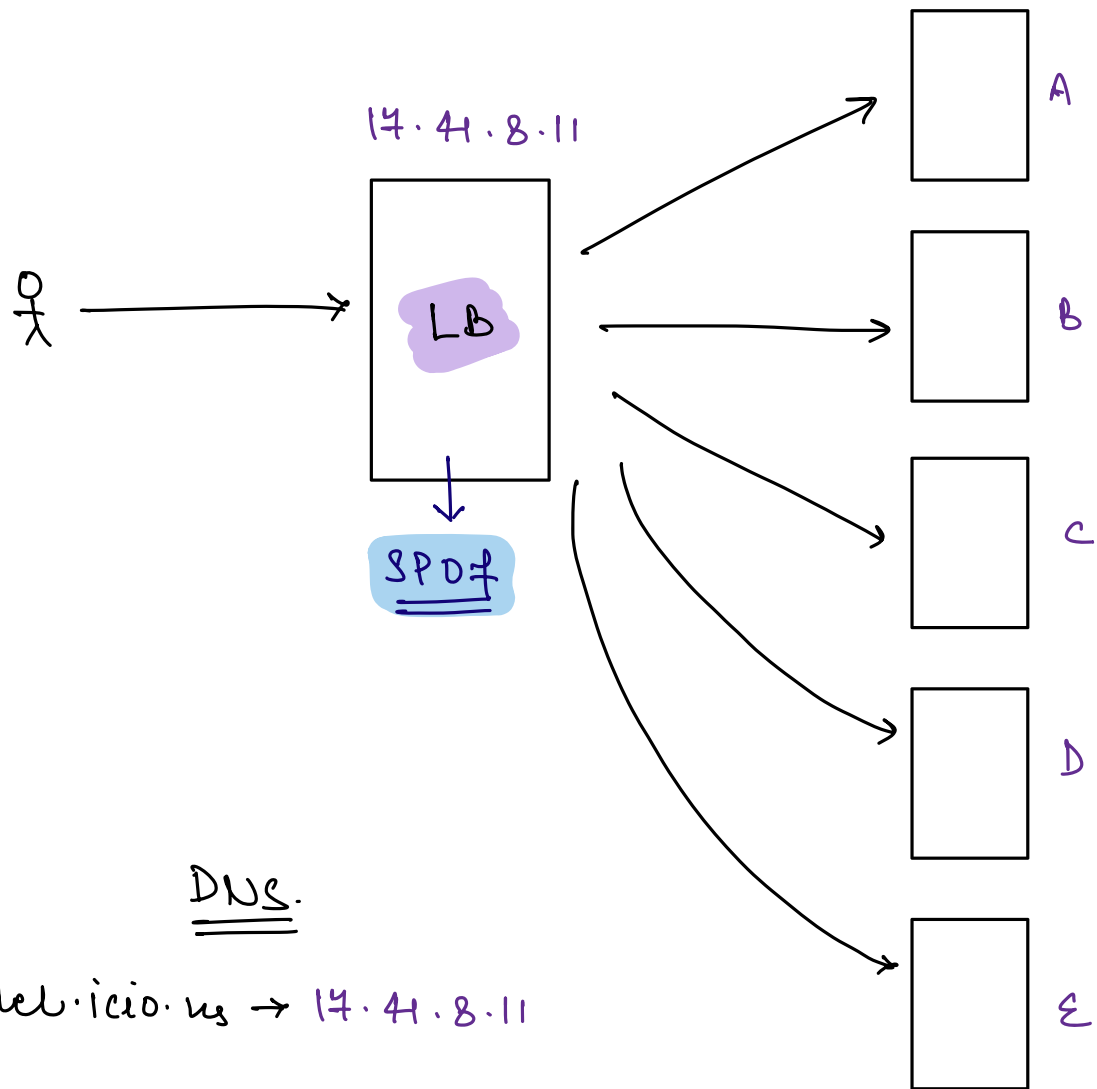

→ load balancing

→ Stateful vs Stateless load balancing

→ Algos for load balancing

↳ Consistent hashing

DNS.

del.icio.us → 14.41.8.11

load balancer : Distribute the traffic among all the servers.

⇒ Instead of having a single LB, we can have multiple LB.

GeoDNS.

8.8.8.8

Google

Stateless vs Stateful LB.

1) Calculator App

Cal (x+y) \rightarrow 2

Stateless

When requests are completely independent of each other.

2) Chat4pt

R1

Q.1 Who was the captain of Indian Cricket team during 2011 WC?

→ MS Dhoni.

R2 Tell me more about him.

Stateful.

↳ When the current request is dependent on the state of the previous request.

1. Random LB.

LB: [A, B, C, D, - - - -]

2. Round Robin

→ Stateless.

→ Equal distribution of load.

→ Easy to maintain.

⇒ Properties of a good LB Algorithm.

→ Equal load distribution

→ fast

→ Easy to maintain at LB.

→ User movement incase a m/c goes down.

3) Least Connection first. → Stateless.

4) less response time. → Stateless.

Stateful LB algo.

Range based Sharding

⇒ Lot of chaos is happening if a m/c goes down.

Modulo based Sharding.

$$\underline{\underline{N=4}}$$

$$X \% 4 = 0, 1, 2, 3$$

$$101 \% 3 = 2$$

$$102 \% 3 = 0$$

$$103 \% 3 = 1$$

$$200 \% 3 = \text{---}$$

⇒ Lot of chaos is happening if a m/c goes down.

Consistent Hashing

⇒

$$H_S(s_1) = s'_1$$

$$H_S(s_2) = s'_2$$

$$H_S(s_3) = s'_3$$

$$H_S(s_4) = s'_4$$

$$\downarrow$$
$$[0, 10^{18}]$$

H_U
 \downarrow
users.

$$H_U \hookrightarrow [0, 10^{18}]$$

⇒ Stateful.

$$H_u(u_i) = u'_i$$

$$S_3 \rightarrow u_5 \quad u_7 \quad u_{10}$$

$$S_2 \rightarrow u_9 \quad u_1 \quad u_4$$

$$S_1 \rightarrow u_6 \quad u_2$$

$$S_4 \rightarrow u_3 \quad u_8$$

\Rightarrow

$$H_s(S_1) = S'_1 = 1000$$

$$= S'_2 = 10^6$$

$$= S'_3 = 10^8$$

$$= S'_4 = 10^{10}$$

Sorted Array.

1000	10^6	10^8	10^{10}
------	--------	--------	-----------

$\rightarrow (u)$

$$H_u(u_1) = (x) = 5 \times 10^6$$

From the Array, just find
the next greater element than
x.

Binary Search

If a server goes down then send the traffic of that server to the next server in the ring.

⇒ Lesser Chaos.

If S_2 goes down, then S_1 gets 2x of traffic.

⇒ S_1 may go down.

If S_1 goes down, then S_4 gets 3x of traffic.

⇒ S_4 may go down.

⇒ Cascading failure.

Solⁿ: Distribute of traffic of server that goes down to all the servers.
